What is claimed is:

1. A clinical method of assessing spinal reposition sense, said method comprising: providing a test subject engaged in thoracolumbar movement, said movement comprising a plurality of flexion positions within a range of motion through the sagittal plane; selecting one said flexion position, said position having a vertical coordinate and a horizontal coordinate;

recording a subject reposition in said sagittal plane, said reposition sensed by said subject responsive to said selected position, said reposition having a vertical coordinate and a horizontal coordinate; and

comparing said reposition with said selected position.

- 2. The method of claim 1 wherein said selected position and said recorded reposition have a horizontal coordinate measured at C7-T4.
- 3. The method of claim 2 wherein said horizontal coordinate is measured at the T4 spinal process.
 - 4. The method of claim 1 wherein said subject is asymptomatic.
- 5. The method of claim 1 wherein said positions are selected from the group consisting of full flexion range of motion, one-third flexion range of motion and two-thirds flexion range of motion.
- 6. The method of claim 1 wherein said recorded reposition comprises an average of said recordations.
- 7. The method of claim 1 wherein said subject reposition is substantially without cutaneous input.

- 8. The method of claim 1 wherein said subject reposition is substantially without visual input.
- 9. A method of using linear coordinates to determine angle of thoracolumbar flexion in the sagittal plane, said method comprising:

positioning a subject seated on a substantially level seating surface;

providing a vertical reference and measuring a vertical linear coordinate at C7-T4 on said subject;

measuring a horizontal linear coordinate from said vertical reference at C7-T4 on said subject, said horizontal coordinate at a right angle to said vertical reference; and

trigonometrically determining an angle of flexion of the thoracolumbar spine in the sagittal plane with said measured linear coordinates.

- 10. The method of claim 9 wherein said subject is seated at a distance apart from said vertical reference.
- 11. The method of claim 9 wherein said subject is positioned throughout a range of motion within the sagittal plane.
- 12. The method of claim 11 wherein said subject is positioned at least one of onethird full flexion and two-thirds full flexion range of motion.
- 13. The method of claim 9 wherein said determination assesses thoracolumbar reposition sense.
- 14. A system for determining thoracolumbar position in the sagittal plane, said system comprising:

a vertical reference component, a horizontal reference component and a reference housing component, said vertical and horizontal reference components positioned substantially perpendicular one to another with said housing component; and

a substantially level seat component supporting said vertical reference component and substantially perpendicular therewith.

- 15. The system of claim 13 wherein said housing component defines at least one aperture therethrough.
- 16. The system of claim 14 wherein said seat component further includes a substantially vertical member a distance apart from said vertical reference component.
- 17. The system of claim 14 wherein said horizontal reference component further includes a leveling device thereon.
- 18. A method of using the system of claim 14 to clinically assess spinal reposition sense, said method comprising:

providing a thoracolumbar measurement system having a vertical reference component, a horizontal reference component and a reference housing component, said vertical and horizontal reference components positioned substantially perpendicular one to another with said housing component, and a substantially level seat component supporting said vertical reference component substantially perpendicular therewith;

engaging a test subject seated on said system in thoracolumbar movement, said movement comprising a plurality of flexion positions within a range of motion through the sagittal plane;

selecting one said flexion position, said position having a vertical coordinate and a horizontal coordinate;

recording a subject reposition in said sagittal plane, said reposition sensed by said subject responsive to said selected position, said reposition having a vertical coordinate and a horizontal coordinate; and

comparing said reposition with said selected position.

- 19. The method of claim 18 wherein said selected position and said recorded reposition have vertical and horizontal coordinates measured at C7-T4 on said subject.
- 20. The method of claim 18 wherein said subject is positioned throughout a range of motion within the sagittal plane.
- 21. The method of claim 18 wherein said subject reposition is substantially without cutaneous input.
- 22. The method of claim 18 wherein said subject reposition is substantially without visual input.
